Question What is the main difference between VSEPR theory and valence bond theory in predicting molecular geometry? VSEPR theory predicts molecular shapes based on electron pair repulsions around the central atom, while valence bond theory explains bonding through overlapping atomic orbitals; VSEPR is more straightforward for geometry prediction, whereas

valence bond theory provides insight into bond formation and hybridization. How does the concept of hybridization relate to molecular geometry? Hybridization involves mixing atomic orbitals to form new hybrid orbitals, which determines the shape of the molecule; for example, sp^3 hybridization leads to a tetrahedral geometry, while sp^2 corresponds to trigonal planar. Which bonding theory best explains the existence of resonance structures in molecules like benzene? Valence bond theory, combined with the concept of delocalized electrons, explains resonance structures by describing electron delocalization over multiple bonding frameworks, stabilizing the molecule. Why are some molecules, like CO_2 , linear despite having double bonds? Molecules like CO_2 are linear due to the VSEPR arrangement of electron pairs around the central atom; the double bonds are arranged to minimize repulsion, resulting in a linear shape with bond angles of approximately 180° . How does electron pair repulsion influence molecular geometry in molecules with lone pairs? Lone pairs exert greater repulsive forces than bonding pairs, causing bond angles to decrease and altering the idealized geometries; for example, in water, lone pairs compress the $H-O-H$ bond angle below 109.5° . What role does molecular geometry play in predicting molecular polarity? Molecular geometry determines the spatial arrangement of polar bonds; if bond dipoles do not cancel out due to symmetry, the molecule is polar; for example, a bent shape like in water results in a polar molecule, whereas linear molecules like CO_2 are nonpolar.
